

## Reader's Question about Corona Tests

Recently I had an antigen test, which immediately showed a positive result. However, a PCR test taken immediately afterwards was negative. These two different results now make me feel very insecure, because I am thinking that the virus must have been in my body if its proteins, that is to say, the protein shell, could be detected in me. What can I learn from these two different results and how should I continue to behave?

An unsettled reader (name known to the editors)

## Answer

Dear unsettled/nervous reader,

We cannot really reassure you, and basically it has to be said that you are really right with your conclusion. Since the antigen test shows the protein, that is to say, the protein shell of the virus, this means that antigens against the virus have formed in your body, which indicates that you have come into contact with the virus at some time in the not too distant past or that you have overcome an infection with corona, even if it did not break out openly and you probably had only minor symptoms or none at all. It is indeed quite possible for a human being to become infected unnoticeably with corona and also without it being detectable, however, he/she can still infect other human beings regardless. However, it should also be said that the antigen test is not too reliable. The PCR test, on the other hand, shows quite reliably whether there is an ACUTE corona disease or not, which was obviously not the case with you when you were tested. But again, the same applies as above, namely that there are human beings in whom the virus cannot be detected. This also conforms with that which Ptaah has explained and that which Billy has explained to us based on your question. Namely, both tests are only reliable to a certain percentage because they cannot detect the human beings who carry the virus but do not fall ill with it and then spread it regardless, which has been known to our science since 1906 (the case of Mary Mallon in New York, also known as Typhoid Mary), but which is obviously neither thought of nor is such a process considered in connection with the rampantly spreading corona disease, because, as a rule, in the cases known so far, bacteria and not viruses were the pathogens. The only thing you can do is to continue to strictly adhere to the safety rules which Ptaah has recommended, namely to consistently wear at least FFP2 masks when dealing with other human beings, to keep your distance (indoors 1-1.5 metres, outdoors up to 5 metres or more depending on wind strength) and to maintain careful body and hand hygiene. Unfortunately, there is nothing more you can do for the time being, because the vaccinations that are so highly praised at present are absolutely to be advised against, because they are not at all safe and can have serious long-term consequences. The Plejaren say about these vaccines that their use at such an early stage after development is irresponsible and negligent because they have not been tested long enough and sufficiently and the tests have not been scientifically monitored in the necessary frame. We are sorry that we cannot really reassure you, but we hope that the sober facts will also help you further in terms of how you should behave.
